Non-Leptonic Decays of B Mesons and Strong Coupling Constants

Gustav Kramer and Cai-Dian Lü*

II Institut für Theoretische Physik, Universität Hamburg, 22761 Hamburg, Germany[†]

Abstract

Non-leptonic decays of B mesons into two mesons or meson resonances are studied on the basis of two versions of simple pole-dominance models involving scalar, vector, pseudoscalar and axial-vector poles. The results are compared with those obtained from the usual factorization model and used to obtain information on strong coupling constants between B meson and one light or one charmed meson, respectively. These coupling constants are compared to results from various QCD sum rule calculations.

1 Introduction

Non-leptonic weak decays of B mesons are very interesting for several reasons. First, CP violation in the B-meson system will eventually give us information about the CP violating phase in the Cabibbo -Kobayashi -Maskawa (CKM) mixing matrix [1]. Second, non-leptonic weak decays will give additional clues for determining the absolute values of the quark mixing parameters, in particular the ratio $|V_{ub}/V_{cb}|$, although it is expected that more solid information will come from semi-leptonic B decays. Last, the dynamics of the non-leptonic weak decays in the framework of the standard model is only poorly understood. One of the problems in calculating the transition amplitudes for non-leptonic weak decays is that one needs to evaluate the hadronic matrix elements of certain four-quark operators which can be done in QCD only with non-perturbative methods. The usual route to calculating these hadronic matrix elements is to start from the effective, QCD corrected, Hamiltonian for the $\Delta b = 1$ non-leptonic decays in the six-quark model, i.e. including the t quark [2, 3, 4]. This gives the weak Hamiltonian in terms of four-quark operators. For computing the hadronic matrix elements of these four-quark operators the factorization approximation is used [5, 6, 7]. Then the hadronic matrix elements are given in terms of current matrix elements (matrix elements of two-quark operators) as they appear also in semi-leptonic decays. These current matrix elements are much easier to calculate and many models [8, 9, 10] have been proposed for them. When these current matrix elements are approximated by a single pole based on the idea of vector dominance we arrive at the pole-dominance model of two-body non-leptonic decays. This model has been applied to the calculation of non-leptonic decays of charmed mesons [11]. Many years ago, this model was used already for the discussion of strange particle decays. In particular, it is known, that this model provides a basis for a description of $K \rightarrow 2\pi$ decays [12].

In this work we apply the pole-dominance model to two-body non-leptonic B decays and show its strong relationship to the usual factorization model [7, 13]. Therefore this latter model will be our starting point where we also use as input the parameters of the current

matrix elements as given in [7]. This allows us to extract various strong coupling constants between B mesons, their vector and axial-vector counterparts, and light and charmed mesons. These coupling constants and also the form factors of the current matrix elements will be compared with other information coming from QCD sum rule and QCD lattice calculations. For simplicity, we consider only the lowest lying poles. The inclusions of higher lying poles would make the extraction of the strong coupling constants impossible.

The outline is as follows: In section 2, we explain the relationship of the usual approach with the pole-dominance model using as example a collection of B decays into two pseudoscalar-mesons ($B \rightarrow PP$). We calculate the two-body branching ratios in parallel for the usual approach and two versions of the pole-dominance framework. In one version we calculate the residues of the poles on the mass shell of the intermediate state. This reproduces the usual approach. The other version follows essentially the work of Bedaque et al.[11] for D decays where a particular off-shell extrapolation has been adopted. These results are compared to experimental data when they are available. In section 3, we proceed to the more complicated $B \rightarrow VP$ and $B \rightarrow VV$ channels, where V are light or charmed vector mesons. Section 4 is reserved for a summary and some conclusions.

2 B decays into two pseudoscalar mesons

To start, we choose as an example for the decays $B \rightarrow PP$, the channel $\bar{B}^0 \rightarrow \pi^+\pi^-$. The relevant effective weak Hamiltonian can be parameterized as

$$\mathcal{H}_{eff} = \frac{4G_F}{\sqrt{2}} [V_{ub}V_{ud}^*(C_1O_1 + C_2O_2)] + h.c., \quad (1)$$

where the C_i (i=1,2) are the short-distance Wilson coefficients defined at a scale μ of the order of the heavy quark mass m_b and the O_i are the local quark operators with the appropriate quantum numbers. For simplicity we have neglected the strong and electroweak penguins. The electroweak penguins are found to give small contributions to the mode $\bar{B}^0 \rightarrow \pi^+\pi^-$. The strong penguins could be included easily [14].

The explicit expressions of the operators O_1 and O_2 are:

$$\begin{aligned} O_1 &= (\bar{d}_\alpha \gamma^\mu L u_\beta)(\bar{u}_\beta \gamma_\mu L b_\alpha), \\ O_2 &= (\bar{d}_\alpha \gamma^\mu L u_\alpha)(\bar{u}_\beta \gamma_\mu L b_\beta), \end{aligned} \quad (2)$$

where α, β are colour indices and $L = \frac{1}{2}(1 - \gamma_5)$. For the Wilson coefficients at the scale $\mu = m_b = 4.8\text{GeV}$ we use the values [14]:

$$C_1 = -0.324 \quad C_2 = 1.150. \quad (3)$$

These coefficients are regularization scheme independent at next-to-leading logarithmic precision as obtained by Buras et al.[15] for $\Lambda_{\overline{MS}}^{(4)} = 350\text{MeV}$. With the factorization hypothesis and after Fierz reordering we obtain from (1) and (2)

$$\langle \pi^+ \pi^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{4G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) \langle \pi^+ | \bar{u} \gamma_\mu L b | \bar{B}^0 \rangle \langle \pi^- | \bar{d} \gamma^\mu L u | 0 \rangle, \quad (4)$$

where N is the number of colours.

The current matrix elements in (4) are evaluated in terms of form factors F_1 and F_0 for the decay $\bar{B}^0 \rightarrow \pi^+ l^- \bar{\nu}_l$ and the pion decay constant $f_\pi = 0.132\text{GeV}$ as follows:

$$\langle \pi^+ | \bar{u} \gamma_\mu L b | \bar{B}^0 \rangle = \frac{1}{2} \left[(p_B + p_\pi)_\mu - \frac{m_B^2 - m_\pi^2}{q^2} q_\mu \right] F_1^{B \rightarrow \pi}(q^2) + \frac{1}{2} \frac{m_B^2 - m_\pi^2}{q^2} q_\mu F_0^{B \rightarrow \pi}(q^2) \quad (5)$$

$$\langle \pi^- | \bar{d} \gamma^\mu L u | 0 \rangle = \frac{i}{2} f_\pi q^\mu \quad (6)$$

where $q = p_B - p_\pi$. With these definitions we get the following result for (4):

$$\langle \pi^+ \pi^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = i \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) f_\pi (m_B^2 - m_\pi^2) F_0^{B \rightarrow \pi}(m_\pi^2) \quad (7)$$

In (5) $F_1(F_0)$ are the form factors of $1^-(0^+)$ (transverse (longitudinal)) projections of the vector current. At $q^2 = 0$, we have $F_0(0) = F_1(0)$ to cancel the pole at $q^2 = 0$ in (5). But F_1 and F_0 differ for arbitrary q^2 . In (7) we need $F_0^{B \rightarrow \pi}$ only for $q^2 = m_\pi^2$, which is small, so that we can set $F_0^{B \rightarrow \pi} = F_1^{B \rightarrow \pi}$. Of course for $F_0^{B \rightarrow \pi}(q^2) = F_1^{B \rightarrow \pi}(q^2)$ with arbitrary q^2 in (5) we obtain the same result. The $1^- (0^+)$ part of the current $(\bar{u} \gamma_\mu L b)$ has the quantum number

of the B^{*-} (B_0^-) meson with mass $m_{B^*} = 5.32\text{GeV}$ ($m_{B_0} = 5.73\text{GeV}$) (We denote the 3P_J bound states by B_J). If according to the vector-meson-dominance model (VDM) the form factor $F_1^{B \rightarrow \pi}$ is dominated by just this 1^- resonance with mass m_{B^*} we have

$$F_1^{B \rightarrow \pi}(q^2) = \frac{g_{B^* B \pi} m_{B^*} f_{B^*}}{m_{B^*}^2 - q^2}. \quad (8)$$

In (8) the current coupling f_{B^*} is defined by the vector current matrix element

$$\langle 0 | \bar{u} \gamma_\mu b | \bar{B}^* \rangle = f_{B^*} m_{B^*} \epsilon_\mu, \quad (9)$$

and the strong coupling is defined through the Lagrangian

$$\mathcal{L}_{B^* B \pi} = g_{B^* B \pi} B_\mu^* B \overset{\leftrightarrow}{\partial}^\mu \pi. \quad (10)$$

Similarly we define the current matrix element of the scalar resonance state B_0^- :

$$\langle 0 | \bar{u} \gamma^\mu b | B_0^- \rangle = i f_{B_0} p_{B_0}^\mu, \quad (11)$$

and the coupling of B_0^- to $\bar{B}^0 \pi^+$ by

$$\mathcal{L}_{B_0 B \pi} = \frac{1}{m_{B_0}} g_{B_0 B \pi} \partial_\mu B_0 B \overset{\leftrightarrow}{\partial}^\mu \pi, \quad (12)$$

$g_{B_0 B \pi}$ is dimensionless. With these definitions the form factor $F_0^{B \rightarrow \pi}(q^2)$ is given in the scalar-meson-dominance model by the formula

$$F_0^{B \rightarrow \pi}(q^2) = \frac{g_{B_0 B \pi} m_{B_0} f_{B_0}}{m_{B_0}^2 - q^2}. \quad (13)$$

With (13) the weak transition matrix element (7) can be written as

$$\langle \pi^+ \pi^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = i \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) f_\pi \frac{m_B^2 - m_\pi^2}{m_{B_0}^2 - m_\pi^2} g_{B_0 B \pi} m_{B_0} f_{B_0}. \quad (14)$$

Here $g_{B_0 B \pi}$ and f_{B_0} are on-shell couplings to the scalar resonance B_0 which is on the mass shell. This means that the off-shell extrapolation factor of the current matrix element is given by just a single pole in (13).

The result (14) for the transition amplitude $\bar{B}^0 \rightarrow \pi^+ \pi^-$ can be obtained more directly from the pole diagram in Fig.1a. In this diagram, the initial $\bar{B}^0$ can go into a $B^{*-} \pi^+$ or

Figure 1: Feynman diagrams for $\bar{B}^0 \rightarrow \pi^+ \pi^-$ in pole model.

$B_0^- \pi^+$ via the strong interaction couplings (10) or (12). The B^{*-} or B_0 converts into a π^- via the weak interaction (1) shown in terms of quark lines in Fig.1b. The weak matrix element is evaluated in the vacuum insertion approximation with the following result for the intermediate B_0^- :

$$\begin{aligned}
\langle \pi^- | \mathcal{H}_{eff} | B_0^- \rangle &= \frac{4G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) \langle \pi^- | \bar{d} \gamma^\mu L u | 0 \rangle \langle 0 | \bar{u} \gamma_\mu L b | B_0^- \rangle \\
&= -\frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) f_\pi m_{B_0}^2 f_{B_0}.
\end{aligned} \tag{15}$$

In (15) $p_{\pi^-} = p_{B_0^-}$ and $p_{B_0^-}^2 = m_{B_0^-}^2$ and the current matrix elements in (6) and (11) have been used. Inserting the propagator of the intermediate B_0^- meson and the strong vertex the result for the decay matrix element is:

$$\langle \pi^+ \pi^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = i \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) f_\pi \frac{m_B^2 - m_\pi^2}{m_{B_0}^2 - m_\pi^2} g_{B_0 B \pi} m_{B_0} f_{B_0}. \tag{16}$$

The result (16) agrees with (14) as to be expected. To achieve this, two ingredients were essential. First, the coupling $B_0 \rightarrow B \pi$ in (12) has such a form that it vanishes for $m_B^2 = m_\pi^2$, i.e. the coupling of a scalar meson to two pseudoscalar mesons of equal masses would be different. Second, in (15) we have set $p_{\pi^-} \cdot p_{B_0^-} = p_{B_0^-}^2 = m_{B_0^-}^2$. This means that the weak transition matrix element $B_0^- \rightarrow \pi^-$ is evaluated at the on-shell point of the intermediate B_0^- resonance, whereas the propagator is calculated at $(p_{\bar{B}^0} - p_{\pi^+})^2 = p_{\pi^-}^2 = m_\pi^2$. This is in the spirit of the meson-dominance approximation and agrees with the result (13) where the form factor $F_0^{B \rightarrow \pi}(q^2)$ is written down directly in this approximation.

In the pole model calculations of ref.[11] a different route has been taken. Instead of the B_0 state the intermediate state is the B^* with spin 1^- . In this case the pole cancels by the factor $m_{B^*}^2 - q^2$ in the numerator and the result is

$$\langle \pi^+ \pi^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = i \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* \left(\frac{1}{N} C_1 + C_2 \right) f_\pi \frac{(m_B^2 - m_\pi^2)}{m_{B^*}} g_{B^* B \pi} f_{B^*}. \quad (17)$$

The difference between (16) and (17) is small since $F_1^{B \rightarrow \pi}(0) = F_0^{B \rightarrow \pi}(0) \simeq F_0^{B \rightarrow \pi}(m_\pi^2)$. It is clear however, that in this evaluation the residue of the pole $1/(m_{B^*}^2 - q^2)$ vanishes like $(m_{B^*}^2 - q^2)$, so that the pole is canceled. This is apparent also from (15) when we evaluate $\langle \pi^- | \mathcal{H}_{eff} | B^{*-} \rangle$ in the vacuum saturation approximation. Then we obtain the factor $\epsilon \cdot p_{\pi^-} = \epsilon \cdot p_{B^*}$ where ϵ is the polarization vector of the B^* . Of course, this factor vanishes on the mass shell. We think that our evaluation of the pole model is more appropriate since the pole is kept, so that our result is correct for $q^2 \rightarrow m_{B_0}^2$. Since a large extrapolation from $q^2 = m_{B_0}^2$ to $q^2 = m_\pi^2$ is involved, one must be careful in the calculation of the numerator.

From (13) we have

$$g_{B_0 B \pi} = \frac{F_0^{B \rightarrow \pi}(0) m_{B_0}}{f_{B_0}}. \quad (18)$$

and a similar equation for $g_{B^* B \pi}$ following from (8).

$F_1^{B \rightarrow \pi}(0) = F_0^{B \rightarrow \pi}(0)$ has been calculated in various approaches: quark model, QCD sum rule and QCD lattice calculations. Thus either from these results or in case the branching ratio for the decay $\bar{B}^0 \rightarrow \pi^+ \pi^-$ becomes precisely known experimentally the relation (16) allows us to calculate the coupling constant $g_{B_0 B \pi}$, if f_{B_0} is determined from other sources. Similarly $g_{B^* B \pi}$ is calculated from $F_1^{B \rightarrow \pi}(0)$, where we need in addition the current coupling f_{B^*} . Since the experimental branching ratio of $\bar{B}^0 \rightarrow \pi^+ \pi^-$ is not very well known yet (see Table 5) we must rely on $F_1^{B \rightarrow \pi}(0) = F_0^{B \rightarrow \pi}(0)$ as calculated in various models. We shall do this later and compare to direct theoretical results for $g_{B_0 B \pi}$ or $g_{B^* B \pi}$.

Our result for the weak transition matrix elements has the factor $a_2 = C_2 + C_1/N$, which should be evaluated with $N=3$. In the following we shall evaluate them with $N=2$ giving $a_2 = 0.988$ using (3). a_2 depends on N only mildly, since $|C_1| < C_2$, so that choosing $N=3$ would give similar results for all colour unsuppressed decays, for which the transition matrix

elements are proportional to a_2 . In the following we shall denote this class of decays by class I. The class II stands for the colour suppressed decays which have matrix elements proportional to $a_1 = C_1 + C_2/N$, which depends strongly on N . The third class is a superposition of class I and class II matrix elements. Recent comparisons of experimental data for many two-body B decays show that on the basis of the factorization hypothesis and BSW matrix elements from [13] a reasonable fit to these data gives $N \simeq 2$ [16]. $N=3$ would produce very bad results for the measured class II decays and the class III decays can be fitted only with a positive a_1 . For example, for $N=2, 3$ or ∞ we have the following values for a_1 using (3): $a_1 = 0.251, 0.059, -0.324$. The choice $N = \infty$ is favored in D decays [7]. The fact, that the choice $N=3$ is not possible points into the direction that so-called non-factorization contributions are significant, in particular in the class II and class III transitions. Of course, it is not certain, that these contributions can universally accounted for by choosing $N=2$. It is more likely that these contributions depend on the particular decay channel. For fits and constraints on the non-factorization terms in various channels see [17]. We also emphasize that the result $N \simeq 2$ from the fit in [16] depends on the BSW [13] choice of transition form factors and current coupling constants. We shall assume $N = 2$ independent in which pole model the weak matrix elements are evaluated. This can be justified empirically since the magnitude and also the sign of a_1 is deduced from such final states, where the two pole models coincide, as will be seen later in our presentation for the PV and VV results. If one gives up the requirement that the C_i should be independent of the regularization scheme one can find short distance coefficients C_1 and C_2 in next-to-leading logarithmic precision which give $a_1 = 0.2$ with $N=3$ by selecting the appropriate scheme [18].

Other class I decays going into two pseudoscalar mesons are $\bar{B}^0 \rightarrow D^- D^+, D_s^- D^+, K^- D^+, \pi^- D^+$ and $B^- \rightarrow D^- D^0, D_s^- D^0$. These decays are calculated from $\mathcal{H}_{eff}$'s where $u \rightarrow c$ and/or $d \rightarrow s$ with the same short distance coefficients as in (3). Of special interest is the decay $\bar{B}^0 \rightarrow \pi^- D^+$ which belongs also to the colour unsuppressed class I. This decay can proceed also through the annihilation diagram. The diagrams in the usual factorization approximation for the quark diagram and for the pole model are shown in Fig.2a and 2b.

Figure 2: The diagrams of $\bar{B}^0 \rightarrow D^+ \pi^-$ in the usual factorization approximation for the quark diagram (a) and for the pole model (b).

In the pole model according to ref.[11], the transition matrix element corresponding to the diagram in Fig.2b is

$$\langle \pi^- D^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle = -i \frac{G_F}{\sqrt{2}} V_{cb} V_{ud}^* \left(\frac{1}{N} C_2 + C_1 \right) f_{B^0} \frac{(m_D^2 - m_\pi^2)}{m_{D^*}^2} g_{D^{*0} D^+ \pi^-} f_{D^*} m_{D^*}. \quad (19)$$

With (8) this can be written as

$$\langle \pi^- D^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle = -i \frac{G_F}{\sqrt{2}} V_{cb} V_{ud}^* a_1 f_{B^0} (m_D^2 - m_\pi^2) F_1^{D \rightarrow \pi}(0). \quad (20)$$

Compared to the dominant pole contribution, which is given by the analogous equation to (14), the annihilation contribution is suppressed by the factor $\frac{m_D^2}{m_B^2} \frac{a_1}{a_2}$ which is approximately 0.03.

The fact that in (20) the pole $1/(q^2 - m_{D^*}^2)$ has canceled against the same factor $(q^2 - m_{D^*}^2)$ in the numerator indicates that the residue of the pole vanishes on the mass shell of the D^{*0} resonance. This is already obvious when one evaluates the weak transition matrix element in the vacuum saturation approximation

$$\langle D^{*0} | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{4G_F}{\sqrt{2}} V_{cb} V_{ud}^* a_1 \langle D^{*0} | \bar{c} \gamma_\mu L u | 0 \rangle \langle 0 | \bar{d} \gamma^\mu L b | \bar{B}^0 \rangle. \quad (21)$$

Table 1: Values of pole masses in GeV.

Current	m(0 ⁻)	m(1 ⁻)	m(1 ⁺)	m(0 ⁺)
$\bar{d}c$	1.8693	2.010	2.4222	
$\bar{u}c$	1.8645	2.0067	2.4222	
$\bar{s}c$	1.9685	2.1124	2.53535	
$\bar{u}b$	5.2789	5.3248	5.37	5.73
$\bar{d}b$	5.2792	5.3248	5.37	5.73
$\bar{s}b$	5.3693	5.41	5.9	5.89
$\bar{c}b$	6.264	6.337	6.730	6.700
$\bar{c}c$	2.9798	3.09688	3.51053	3.4151

The first current matrix element in (21) is proportional to the polarization vector of the D^{*0} whereas the second current matrix element is proportional to $p_{B^0}^\mu = p_{D^{*0}}^\mu$, so that the product vanishes. This indicates, that the pole-model calculation of the annihilation contribution is also ambiguous.

If we start from the quark diagram in Fig.2a and do the vacuum insertion approximation, but then evaluate the matrix element $\langle \pi^- D^+ | \bar{c} \gamma_\mu L u | 0 \rangle$ directly in terms of the form factor $F_0^{D \rightarrow \pi}(q^2)$ we obtain the usual result:

$$\begin{aligned}
\langle \pi^- D^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle &= -i \frac{G_F}{\sqrt{2}} V_{cb} V_{ud}^* a_1 f_{B^0} (m_D^2 - m_\pi^2) F_0^{D \rightarrow \pi}(m_B^2) \\
&= -i \frac{G_F}{\sqrt{2}} V_{cb} V_{ud}^* a_1 f_{B^0} (m_D^2 - m_\pi^2) F_0^{D \rightarrow \pi}(0) \frac{m_{D_0}^2}{m_{D_0}^2 - m_B^2}.
\end{aligned} \tag{22}$$

This means that the annihilation contribution is suppressed further by the additional factor $m_{D_0}^2/(m_B^2 - m_{D_0}^2)$, which results from the fact that in (22) the current transition form factor is highly off-shell at $q^2 = m_B^2$, whereas the off-shell extrapolation in the pole diagram is determined by the mass of the D^{*0} . It is clear that the pole-model calculation starting from Fig.2a with a 0^+ intermediate state leads to the same result (22).

Such an annihilation contribution is in principle also possible for $\bar{B}^0 \rightarrow \pi^+ \pi^-$. But it

vanishes since the particles in the final state have equal masses.

We conclude that the pole-model calculation of the non-annihilation diagrams as depicted in Fig.1a agrees with the usual calculations of the $B \rightarrow PP$ decays where the form factors are approximated by a single pole (compare (14) with (16)). If a different off-shell extrapolation as advocated in ref.[11] is assumed we obtain the result (17) which differs actually very little from (16) since $F_0^{B \rightarrow \pi}(0) = F_1^{B \rightarrow \pi}(0)$ and the extrapolation of $F_0^{B \rightarrow \pi}(q^2)$ from $q^2 = 0$ to $q^2 = m_\pi^2$ has only a small effect. Of course, this is different for decays like $\bar{B}^0 \rightarrow D^- D^+, D_s^- D^+$, for which the form factor $F_0^{B \rightarrow D}(q^2)$ must be computed for $q^2 = m_D^2$, which differs from $F_1^{B \rightarrow D}(0)$ to be inserted into (17).

Class II decays are $\bar{B}^0 \rightarrow \pi^0 \pi^0, \pi^0 D^0, \bar{K}^0 \eta_c$, and $B^- \rightarrow K^- \eta_c$. The decays $B^- \rightarrow \pi^- \pi^0, \pi^- D^0$ and $K^- D^0$ are class III decays, where contributions of colour suppressed and unsuppressed matrix elements interfere.

To obtain an overview on expected branching ratios for all these decays we shall present results in two schemes: (i) the pole-model calculation in the form (14) which is equal to the usual quark diagram computation in terms of form factors $F_0(0)$; (ii) the pole model result (17) where the pole canceled and the result depends on $F_1(0)$. In scheme (i) the annihilation contribution which occurs in some channels is negligible, either due to strong suppression in the quark diagram result (22) or due to the same suppression for the pole model. In scheme (ii) we evaluate the annihilation diagram with the formula (20) which involves a different off-shell extrapolation of the residue of the pole. It is clear that in this form the annihilation terms are larger. The scheme (i) will be denoted BSW model since the pole model calculation agrees with the usual computation and the scheme (ii) will be denoted pole model.

For these calculations we need the values of the masses of the particles in the initial and final states and of the pole positions together with the pseudoscalar (f_M) and vector meson (f_V) decay constants. The masses are taken from the PDG tables [19] or from the table in [7]. The decay constants f_M and f_V for pseudoscalar and vector mesons, respectively are taken from the following sources. f_π, f_K, f_ρ and f_{K^*} are taken from [7]. $f_{D_s} = 288 \text{ MeV}$ corresponds to the CLEO measurement [20] of the leptonic decay of the D_s^- . We assume

Table 2: Values of decay constants.

Particle	f_M (MeV)	Particle	f_V (MeV)
π	133	ρ	221
K	162	K^*	221
D	250	D^*	250
D_s	288	D_s^*	288
B	140	B^*	160
B_s	158	B_s^*	181
B_c	360	B_c^*	320
η_c	393	J/ψ	382

$f_{D_s^*} = f_{D_s}$ and fix f_D by the ratio $f_{D_s}/f_D = 1.15$, which is the average value of this ratio obtained in various lattice calculations [21]. $f_D = f_{D^*}$ is also fixed by assumption. f_B and f_{B^*} are from QCD sum rule calculations in [22]. The values for f_{B_s} and $f_{B_s^*}$ are fixed by the ratio $f_{B_s}/f_B = f_{B_s^*}/f_{B^*} = 1.13$ from [21]. The values for f_{B_c} and $f_{B_c^*}$ have been found in [23]. The ratio of $f_{\eta_c}^2/f_{J/\psi}^2 = 1.06$ is found in [24] and $f_{J/\psi}$ is determined from the leptonic width of the J/ψ as in [7]. Of course, most of these values for the decay constants are not definite yet and somewhat other choices can be made. This information is collected in Table 1 (masses) and Table 2 (decay constants). The form factors $F_1(0) = F_0(0)$ are written down in Table 3, also taken from [7]. The CKM matrix elements are given in Table 4, together with the B^0 and B^- lifetime data [19]. Our results for the branching ratios in the pole model and the BSW model are collected in Table 5. In this table we also give the amplitudes for the BSW and for the pole model which show in particular the contributions proportional to a_1 and a_2 for the class III decays. For some of the channels the branching ratios have been measured. The world-average values are reported in [16]. For other channels some new measurements and upper limits exist [25]. These data are given in the last column of Table 5.

From the results in Table 5, we observe the following. Pole model and BSW results lie

very near together. Exceptions are the decays $B^- \rightarrow D^- D^0$, $D_s^- D^0$ and $\bar{B}^0 \rightarrow D^- D^+$, $D_s^- D^+$ which differ due to the extrapolation of $F_0^{B \rightarrow D}$ from $q^2 = 0$ to $q^2 = m_D^2$. The annihilation contribution in $\bar{B}^0 \rightarrow \pi^- D^+$ has little effect. However, it is significant for the decay $\bar{B}^0 \rightarrow \pi^0 D^0$, where it is proportional to the same Wilson coefficient a_1 as the direct contribution. Except for the decay $\bar{B}^0 \rightarrow D_s^- D^+$ we observe very good agreement between the calculated and the measured branching ratios. Both pole model versions agree with the data, so that they can not be utilized to exclude for example the model based on ref.[11].

For the results in Table 5 we needed the values of three form factors $F_1^{B \rightarrow D}$, $F_1^{B \rightarrow \pi}$ and $F_1^{B \rightarrow K}$ taken from Table 3. Since only for four channels, namely $B^- \rightarrow D_s^- D^0$, $\pi^- D^0$ and $\bar{B}^0 \rightarrow D_s^- D^+$, $\pi^- D^+$, experimental branching ratios exist, we gain only information on $F_1^{B \rightarrow D}(0)$ and $F_1^{B \rightarrow \pi}(0)$. Since our results agree quite well with the measured data we are confident that the BSW values for these form factors are reasonable. In this connection it is of interest to search in the literature for other theoretical predictions on these form factors. Such predictions based on various methods are collected in Table 6 for $F_1^{B \rightarrow \pi}(0)$ and in Table 7 for $F_1^{B \rightarrow D}(0)$. The values for $F_1^{B \rightarrow \pi}$ with two exceptions are very similar. Calculations using similar methods give approximately the same result. Furthermore the values predicted from QCD sum rules and constituent quark models of various kinds are very near together and agree with the average value obtained from QCD lattice calculations. From the comparison in Table 6 we are confident that $F_1^{B \rightarrow \pi}(0) \simeq 0.3$ is a reasonable value which agrees also with the recent measurement of the branching ratio for $B^0 \rightarrow \pi^- l^+ \nu$ [34]. $F_1^{B \rightarrow \pi}(0) = 0.37 \pm 0.05$ is deduced from the measured branching ratio, using $|V_{ub}| = 0.0035$ from Table 4 and the pole masses from Table 1. This value depends on the way the q^2 dependence of the form factor is parameterized. We assumed for consistency the approximation with one pole. Results with other form factor assumptions can be found, for example, in [26].

The situation is similar for the form factor $F_1^{B \rightarrow D}(0)$. The results obtained from quark models agree quite well and agree nicely with the value calculated from the measured branching ratio $B(B^0 \rightarrow D^- l^+ \nu_l) = (1.9 \pm 0.5) \times 10^{-2}$ [19]. Of course, the experimental value $F_1^{B \rightarrow D}(0) = 0.71 \pm 0.10$ and also the results obtained from the Isgur -Wise normalization [39]

in the HQET depend on the assumed q^2 variation of $F_1^{B \rightarrow D}$. The results in Table 7 under f and g are obtained with single-pole approximation with masses from Table 1. Somewhat smaller values as from the extrapolation with the single-pole formula are obtained with the usual exponential extrapolation to $q^2 = 0$ on the basis of slope calculations from QCD sum rules or lattice calculations or from fits to the experimental data of $B \rightarrow D^* l \nu$ decays [40]. Taking into account that the Isgur-Wise normalization is $\xi(1) = 0.91 \pm 0.04$ [40] due to mass and perturbative QCD effects one arrives at $F_1^{B \rightarrow D}(0) \simeq 0.61$, instead of $F_1^{B \rightarrow D}(0) = 0.71$ in Table 7. We conclude that the BSW value is a good average.

We are now in the position to calculate $g_{B^* B \pi}$, $g_{B_s^* B K}$ and $g_{B_c^* B D}$ from (18). To be definite we use the BSW values of the corresponding form factors from Table 3 together with the decay constants from Table 2. We obtain for the strong VPP coupling constants $g_{B^* B \pi} = 11.1$, $g_{B_s^* B K} = 11.7$, and $g_{B_c^* B D} = 13.7$. Surprisingly, these three couplings lie close together, so that the spread of the form factors $F_1^{B \rightarrow P}(0)$ ($P = \pi, K, D$) is mostly due to the different values of f_{B^*} , $f_{B_s^*}$ and $f_{B_c^*}$ and the different mass values. If we take $f_{B_c^*} = 0.400 \text{ GeV}$, i.e. the upper limit of the QCD sum rule result [23] we obtain $g_{B_c^* B D} = 11.0$. In potential model calculations $f_{B_c^*}$ comes out even larger: $f_{B_c^*} \simeq 0.5 \text{ GeV}$ [41]. Results for

$g_{B^*B\pi}$ based on QCD sum rule calculations or on the quark model with chiral HQET are collected in [22]. Our result $g_{B^*B\pi} = 11.1$ can be compared with various QCD sum rule calculations. The calculations use different approaches. They are either based on expansions near the light-cone or use the short-distance expansion in connection with the soft pion limit. Results obtained with the first method are $g_{B^*B\pi} = 14 \pm 3$ [22], $g_{B^*B\pi} = 10 \pm 2$ [42], $g_{B^*B\pi} = 10.4 \pm 2.0$ [43], and $g_{B^*B\pi} = 7 \pm 2$ [44]. The second method has given the following results: $g_{B^*B\pi} = 14.5 \pm 1.5$ [22] and $g_{B^*B\pi} = 11.2 \pm 2.0$ [45]. These results depend on the values obtained for f_B and f_{B^*} , which are also taken from QCD sum rule calculations. In [42, 43, 45] these constants are $f_B = (150 \pm 20)\text{MeV}$ and $f_{B^*} = (190 \pm 10)\text{MeV}$. This explains, for example, the different results in [22] and [45] with the light-cone sum rule. In the original result for $f_B f_{B^*} g_{B^*B\pi}$, as it follows from the sum rule, the two evaluations gave the same result, namely $f_B f_{B^*} g_{B^*B\pi} = 7.9 \times 10^{-3} \text{GeV}^2$. The smaller value of $g_{B^*B\pi}$, obtained by Narison et al. [44] is due to the fact, that these authors included $O(\alpha_s)$ corrections to the heavy meson decay constants which result in larger values for f_B and f_{B^*} . Taking all these uncertainties into account the value of $g_{B^*B\pi}$ obtained from the non-leptonic decays agrees reasonably well with the QCD sum rule results.

To our knowledge there exist no QCD sum rule calculations for $g_{B_s^*BK}$ and $g_{B_c^*BD}$ to which we could compare our results.

Actually in the BSW pole model the decay amplitude depends on the form factor $F_0^{B \rightarrow \pi}(0)$ (see (7)) not $F_1^{B \rightarrow \pi}(0)$. At $q^2 = 0$ we have $F_0^{B \rightarrow \pi}(0) = F_1^{B \rightarrow \pi}(0)$ which yields an equation for $g_{B_0B\pi}$ in terms of $g_{B^*B\pi}$:

$$g_{B_0B\pi} = \frac{m_{B_0} f_{B^*}}{m_{B^*} f_{B_0}} g_{B^*B\pi} \quad (23)$$

i.e. $g_{B_0B\pi} \simeq g_{B^*B\pi}$. Inserting masses and assuming $f_{B_0} = f_B$, we obtain $g_{B_0B\pi} = 13.7$. This result can be compared with a recent QCD sum rule calculation of this coupling constant [46]. Adjusting their result to $f_B = f_{B_0} = 0.14\text{GeV}$ and to our definition of the $B_0B\pi$ coupling in (12) the result in [46] is $g_{B_0B\pi} = 4.5$ and $g_{B_0B\pi} = 6.3$ depending on the QCD sum rule method used. These values are more than a factor of two smaller than our result.

Figure 3: Feynman diagrams for $\bar{B}^0 \rightarrow \pi^+ \rho^-$ (a) and for $\bar{B}^0 \rightarrow \pi^- \rho^+$ (b) in pole model.

It is clear that these sum rule results are not compatible with the relation (23). Since our coupling (12) and the $B_0 B \pi$ coupling used in [46] have different off-shell extrapolations it is also not clear to us whether this has any effect on the sum rule evaluation.

We conclude that the coupling constant $g_{B^* B \pi}$ obtained from non-leptonic decay data is in reasonable agreement with QCD sum rule results. The coupling constants $g_{B_s^* B K}$ and $g_{B_c^* B D}$ have rather similar values to $g_{B^* B \pi}$. It would be interesting to know whether these relations can be explained in the framework of QCD sum rule calculations.

3 B decays into pseudoscalar and vector and two vector mesons

First, we consider decays of B mesons into one vector and one pseudoscalar meson: $B \rightarrow VP$. As examples we choose $\bar{B}^0 \rightarrow \pi^+ \rho^-$ and $\bar{B}^0 \rightarrow \pi^- \rho^+$, the analogous channels to the decay considered in the previous section. The pole model diagram for $\bar{B}^0 \rightarrow \pi^+ \rho^-$ is shown in Fig.3a. The intermediate state is the B^* resonance which decays weakly into a ρ^- meson.

The result of the pole model evaluation is

$$\langle \pi^+ \rho^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 m_\rho f_\rho \epsilon^* \cdot (p_B + p_\pi) \frac{g_{B^* B \pi} f_{B^*} m_{B^*}}{m_{B^*}^2 - m_\rho^2}, \quad (24)$$

which can be written as

$$\langle \pi^+ \rho^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 m_\rho f_\rho \epsilon^* \cdot (p_B + p_\pi) F_1^{B \rightarrow \pi}(m_\rho^2), \quad (25)$$

using the vector-dominance relation (8) for the form factor $F_1^{B \rightarrow \pi}$. This result is identical to the result of the usual quark model calculation of BSW. It is clear that an intermediate scalar resonance B_0 gives a vanishing transition matrix element. So, for this case the two pole model calculations yield a unique result. The same formula applies to the decays $\bar{B}^0 \rightarrow D^+ D_s^{*-}$, $D^+ D^{*-}$, $D^+ \rho^-$ and $D^+ K^{*-}$.

For the decay $\bar{B}^0 \rightarrow \pi^- \rho^+$, we need in the usual calculation from the quark diagram the axial-vector current matrix element between $\bar{B}^0$ and ρ^+ . This is parameterized by three invariant form factors A_0 , A_1 and A_2 [8]:

$$\begin{aligned} \langle \rho^+ | \bar{u} \gamma_\mu \gamma_5 b | \bar{B}^0 \rangle &= i \left(\epsilon_\mu^* - \frac{\epsilon^* \cdot q}{q^2} q_\mu \right) (m_B + m_\rho) A_1^{B \rightarrow \rho}(q^2) \\ &- i \left((p_B + p_\rho)_\mu - \frac{(m_B^2 - m_\rho^2)}{q^2} q_\mu \right) (\epsilon^* \cdot q) \frac{A_2^{B \rightarrow \rho}(q^2)}{m_B + m_\rho} \\ &+ i \frac{2m_\rho (\epsilon^* \cdot q)}{q^2} q_\mu A_0^{B \rightarrow \rho}(q^2), \end{aligned} \quad (26)$$

where $q = p_B - p_\rho = p_\pi$ and ϵ^* is the polarization vector of the ρ^+ . To cancel the poles at $q^2 = 0$, we must have

$$2m_\rho A_0^{B \rightarrow \rho}(0) = (m_B + m_\rho) A_1^{B \rightarrow \rho}(0) - (m_B - m_\rho) A_2^{B \rightarrow \rho}(0). \quad (27)$$

With (26) we obtain for the weak transition matrix element the usual result:

$$\langle \pi^- \rho^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 f_\pi (\epsilon^* \cdot p_{\pi^-}) 2m_\rho A_0^{B \rightarrow \rho}(m_\pi^2). \quad (28)$$

The form factor $A_0^{B \rightarrow \rho}$ can be approximated by a single pole with spin 0^- . Analogously to (8) and (13) this meson-dominance approximation yields

$$A_0^{B \rightarrow \rho}(q^2) = \frac{g_{BB\rho} f_B m_B^2}{(m_B^2 - q^2) m_\rho}. \quad (29)$$

The intermediate state is the well known B^- particle with mass m_B . When we evaluate the pole-model diagram in Fig.3b with an intermediate 0^- particle directly we obtain the same result, namely

$$\langle \pi^- \rho^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 f_\pi (\epsilon^* \cdot p_{\pi^-}) \frac{2g_{BB\rho} f_B m_B^2}{m_B^2 - m_\pi^2}. \quad (30)$$

For the calculation with a 1^+ resonance B_1 as intermediate state in Fig.3b, following ref.[11], we need the coupling between the ρ , the B and this resonance. This coupling has the following form

$$\mathcal{L}_{BB_1\rho} = g_s m_{B_1} B B_1^\mu \rho_\mu + \frac{g_d}{m_{B_1}} [B(\partial^\mu B_1^\nu) \partial_\nu \rho_\mu - (\partial_\nu B)(\partial^\mu B_1^\nu) \rho_\mu], \quad (31)$$

which leads to the following matrix element for the transition $\bar{B}^0 \rightarrow B_1^- \rho^+$:

$$\langle B_1^- \rho^+ | \bar{B}^0 \rangle = g_s m_{B_1} \epsilon_{B_1}^* \epsilon_\rho^* - \frac{g_d}{m_{B_1}} [\epsilon_{B_1}^* \cdot (p_B + p_\rho)] (\epsilon_\rho^* \cdot p_{B_1}). \quad (32)$$

With these definitions for the two couplings proportional to g_s (s-wave transition) and g_d (d-wave transition) the weak transition matrix element becomes

$$\langle \pi^- \rho^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle = \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 f_\pi (\epsilon^* \cdot p_{\pi^-}) \left[g_s f_{B_1} - \frac{m_B^2 - m_\rho^2}{m_{B_1}^2} g_d f_{B_1} \right]. \quad (33)$$

In analogy to (29) we relate the strong couplings in (33) to the transition form factors $A_1(0)$ and $A_2(0)$ appearing in the current matrix elements of the axial-vector current as defined in (26):

$$\begin{aligned} g_s f_{B_1} &= (m_B + m_\rho) A_1^{B \rightarrow \rho}(0), \\ g_d f_{B_1} &= \frac{m_{B_1}^2}{(m_B + m_\rho)} A_2^{B \rightarrow \rho}(0). \end{aligned} \quad (34)$$

Then (33) can be written in terms of A_1 and A_2 or A_0 :

$$\begin{aligned} \langle \pi^- \rho^+ | \mathcal{H}_{eff} | \bar{B}^0 \rangle &= \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 f_\pi (\epsilon^* \cdot p_{\pi^-}) \left[(m_B + m_\rho) A_1^{B \rightarrow \rho}(0) - (m_B - m_\rho) A_2^{B \rightarrow \rho}(0) \right] \\ &= \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* a_2 f_\pi (\epsilon^* \cdot p_{\pi^-}) 2m_\rho A_0^{B \rightarrow \rho}(0). \end{aligned} \quad (35)$$

In (33) the pole at $q^2 = m_\pi^2 = m_{B_1}^2$ has canceled, as to be expected. The final result (35) differs from (28) only due to the cancelation of the pole, so that $A_0^{B \rightarrow \rho}$ is to be evaluated at $q^2 = 0$ instead of $q^2 = m_\pi^2$ in (28). It is clear that this change makes only a small difference since $A_0^{B \rightarrow \rho}(m_\pi^2) \simeq A_0^{B \rightarrow \rho}(0)$.

The relation between the two different calculations of the pole diagram in Fig.3b is quite analogous to the results obtained for $\bar{B}^0 \rightarrow \pi^+\pi^-$ in the previous section. We obtain analogous results for the decays $\bar{B}^0 \rightarrow D^{*+}D_s^-$, $D^{*+}D^-$, $D^{*+}\pi^-$ and $D^{*+}K^-$. Of course, for some of these channels the results (28) and (35) differ by a larger amount, since in (28) the form factor $A_0^{B \rightarrow D^*}$ must be calculated for a larger q^2 instead of $q^2 = 0$ in (35).

Similarly to the decay channel $\bar{B}^0 \rightarrow D^+\pi^-$ we have also contributions of the annihilation diagram for the channels $\bar{B}^0 \rightarrow D^+\rho^-$ and $\bar{B}^0 \rightarrow D^{*+}\pi^-$. If we evaluate them with the usual BSW approach or in the pole model with intermediate 0^- poles we obtain a contribution proportional to $A_0^{D \rightarrow \rho}(m_B^2)$ for $\bar{B}^0 \rightarrow D^+\rho^-$ and $A_0^{D^* \rightarrow \pi}(m_B^2)$ for the channel $\bar{B}^0 \rightarrow D^{*+}\pi^-$. These form factors, which must be evaluated at $q^2 = m_B^2$, are suppressed. Therefore we shall neglect the annihilation contributions as we have done also for the $\bar{B}^0 \rightarrow D^+\pi^-$ decay. Only when we follow ref.[11], where the pole term is canceled by the same factor in the numerator, we arrive at a somewhat larger result which can be expressed again by $A_0^{D \rightarrow \rho}(0)$ and $A_0^{D^* \rightarrow \pi}(0)$, respectively. For example, for the channel $\bar{B}^0 \rightarrow D^+\rho^-$ the final result is:

$$\langle D^+\rho^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle = -\frac{G_F}{\sqrt{2}} V_{cb} V_{ud}^* a_1 f_B (\epsilon^* \cdot p_{D^+}) 2m_\rho A_0^{D \rightarrow \rho}(0). \quad (36)$$

To derive this result we used the strong coupling Lagrangian for the coupling of the 1^+ resonance D_1^0 to $D^+\rho^-$ and then introduced $A_1^{D \rightarrow \rho}$ and $A_2^{D \rightarrow \rho}$ with (34). A similar formula as (36) can be derived for the annihilation term of the decay $\bar{B}^0 \rightarrow D^{*+}\pi^-$.

In the same way we calculate the class I decays of the charged B^- . These are the channels $B^- \rightarrow D^0 D_s^{*-}$ and $D^0 D^{*-}$, which have amplitudes proportional to $F_1^{B \rightarrow D}$, and the channels $B^- \rightarrow D^{*0} D_s^-$ and $D^{*0} D^-$ with amplitudes proportional to $A_0^{B \rightarrow D^*}$.

The class II decays with amplitudes proportional to a_2 are calculated in the same way. The amplitudes are either proportional to F_1 or to A_0 . The decays $\bar{B}^0 \rightarrow \pi^0 J/\psi$, $\bar{K}^0 J/\psi$

Table 8: $B \rightarrow PV$ class I decay amplitudes(10^{-7}) and branching ratios in two versions of pole models and experimental measured branching ratios or upper limits (90% C.L.) [16, 25, 48].

and $B^- \rightarrow \pi^- J/\psi$, $K^- J/\psi$ belong to the first group. The second group consists of the decays $\bar{B}^0 \rightarrow \rho^0 \eta_c$, $\bar{K}^{*0} \eta_c$ and $B^- \rightarrow \rho^- \eta_c$, $K^{*-} \eta_c$. Other class II decays are the channels $\bar{B}^0 \rightarrow D^{*0} \pi^0$, $D^0 \rho^0$ and $\bar{B}^0 \rightarrow \rho^0 \pi^0$.

The class III decays with amplitudes coming from both operators O_1 and O_2 are the following: $B^- \rightarrow D^0 \rho^-$, $D^0 K^{*-}$ and $B^- \rightarrow D^{*0} \pi^-$, $D^{*0} K^-$ originating from $b \rightarrow c$ transitions. The channels of class III with $b \rightarrow u$ transitions are $B^- \rightarrow \rho^0 \pi^-$ and $\rho^- \pi^0$.

We have calculated all these decays again in the two versions, (i) pole model without canceling of the pole of the intermediate state, which gives the same results as the usual BSW calculation and (ii) pole-model in the form as introduced in ref.[11]. This model has

a larger annihilation contribution and in the direct contribution, where the 0^- intermediate state is replaced by the 1^+ state, the form factor is evaluated at $q^2 = 0$ instead of $q^2 = m_\pi^2$ or $q^2 = m_D^2$ as it appears in version (i).

The results for the class I decays are collected in Table 8 and for the class II and class III decays in Table 9. In these two tables, the amplitudes are defined without the factor of $(\epsilon \cdot p_\pi)$ in (30). In Table 8, four of the decay channels can be compared to experimental data. In all four channels the agreement is rather good. Unfortunately the experimental errors for the $D^{(*)}D_s^{(*)}$ final states are rather large. For $\bar{B}^0 \rightarrow \pi^- D^{*+}$ the error is smaller and only the prediction of the BSW pole model agrees with the experimental number. The prediction of the pole model with canceling residues is a factor of two smaller than the experimental branching ratio. This is due to the additional annihilation contribution in this model which is too large when compared with the experimental branching ratio. Since in this model the off-shell extrapolation of the form factor to the $q^2 = m_B^2$ is neglected the discrepancy with the data is not unexpected. Actually the disagreement of this pole model in the case of $\bar{B}^0 \rightarrow \pi^- D^{*+}$ is a strong argument against this version of pole model. Of course, this depends on the values assumed for a_1 and a_2 , i.e. our assumption $N = 2$ also in this pole model. If a_1 would be decreased as it happens for example, with $N = 3$, i.e. in pure factorization with colour-octet terms omitted, the annihilation term can be suppressed. However, as we shall see later, this leads to strong disagreement in other channels, where the two pole model versions have identical results. From this comparison it is clear that the extra form factor in the annihilation diagram must be taken into account also in this pole model. This makes these contributions negligible also. This decay gives us a good value for $A_0^{B \rightarrow D^*}(0)$. We notice also that the prediction for $\bar{B}^0 \rightarrow D_s^- D^{*+}$ agrees in the BSW-pole-model slightly better with the experimental number than in the other pole model. In this case the different results in the two models come only from the usual W emission graph.

As already mentioned above, the two pole models give identical results for the decay channels $\bar{B}^0 \rightarrow D^+ K^{*-}$, $D^+ D^{*-}$, $D^+ D_s^{*-}$ and $\pi^+ \rho^-$. Differences occur for the decays $\bar{B}^0 \rightarrow D^- D^{*+}$ and $D_s^- D^{*+}$.

Table 9: $B \rightarrow PV$ class II and III decay amplitudes(10^{-7}) and branching ratios in two versions of pole models and experimental measured branching ratios or upper limits (90% C.L.) [16, 25, 48].

In Table 9, our results for the branching ratios of the decays $\bar{B}^0 \rightarrow \bar{K}^0 J/\psi$ and $B^- \rightarrow K^- J/\psi$ are somewhat smaller than the measured branching ratios. The factor r needed to achieve agreement is $r = 1.7 \pm 0.3$ for $\bar{B}^0 \rightarrow \bar{K}^0 J/\psi$ and $r = 2.0 \pm 0.2$ for $B^- \rightarrow K^- J/\psi$, respectively. Since the Wilson coefficient a_1 is already constrained by the class III decays the disagreement means either a $(30 - 40)\%$ larger value for $F_1^{B \rightarrow K}(0)$ or a breakdown of the factorization assumption [17]. It is clear that other values for a_1 , which for example for $N = 3$ in the pure factorization approach with colour octet terms neglected are obtained, would give very bad results for both pole models. For some of the other decays of class II upper limits for the branching ratios exist which are all obeyed by the theoretical results.

The prominent class III decays are $B^- \rightarrow \rho^- D^0$ and $B^- \rightarrow \pi^- D^{*0}$. The predictions agree quite well with the experimental branching ratios. It is clear that this agreement, given the matrix elements of BSW, is only possible, if a_1 is positive, as was already found in ref.[16]. This statement is again independent of the form of pole model applied in the calculation. Concerning matrix elements these two decays depend on $F_1^{B \rightarrow D}$, $F_1^{B \rightarrow \pi}$, $A_0^{B \rightarrow \rho}$ and $A_0^{B \rightarrow D^*}$.

Next we consider the $B \rightarrow VV$ decays. For these decays the two pole-model versions give identical results which are the same as in the quark diagram approach. So, we need not write down all the formulas. We do this only for one channel $\bar{B}^0 \rightarrow \rho^+ \rho^-$ to fix our notation. The axial part of the current matrix element was already written in (26). In addition we need also the matrix element of the vector current which we write as usual

$$\langle \rho^+ | \bar{u} \gamma_\mu b | \bar{B}^0 \rangle = \epsilon_{\mu\nu\alpha\beta} \epsilon^{\nu*} p_B^\alpha p_\rho^\beta \frac{2V(q^2)}{(m_B + m_\rho)}. \quad (37)$$

With this, (9) and (26) we obtain for the weak transition matrix element

$$\begin{aligned} \langle \rho^+ \rho^- | \mathcal{H}_{eff} | \bar{B}^0 \rangle &= \frac{G_F}{\sqrt{2}} V_{ub} V_{ud}^* (-i f_\rho m_\rho) \left\{ \epsilon^*(\rho^+) \epsilon^*(\rho^-) (m_B + m_\rho) A_1^{B \rightarrow \rho}(m_\rho^2) \right. \\ &\quad - (\epsilon^*(\rho^+) \cdot p_B) (\epsilon^*(\rho^-) \cdot p_B) \frac{2A_2^{B \rightarrow \rho}(m_\rho^2)}{(m_B + m_\rho)} \\ &\quad \left. - i \epsilon_{\mu\nu\alpha\beta} \epsilon^{\mu*}(\rho^-) \epsilon^{\nu*}(\rho^+) p_B^\alpha p_{\rho^+}^\beta \frac{2V^{B \rightarrow \rho}(m_\rho^2)}{(m_B + m_\rho)} \right\}. \end{aligned} \quad (38)$$

So, the transition matrix element is a linear combination of the form factor A_1 , A_2 and V which determine the transition in the s, d and p waves respectively [47].

We have calculated the branching ratios for various decays using the form factor values given in Table 3 together with the decay constants in Table 2 and the pole masses from Table 1. The results are given in Table 10 and are compared to the experimental branching ratios (last column in Table 10). The decay channels in Table 10 are ordered according to class I, II and III as in the previous tables. The calculated branching ratios agree well with the experimental data, in particular for the decays $\bar{B}^0 \rightarrow D^{*+} \rho^-$, $D^{*+} D_s^{*-}$ and $B^- \rightarrow D^{*0} D_s^{*-}$ which are class I decays and $B^- \rightarrow \rho^- D^{*0}$ which is a class III decay. The class II decays $\bar{B}^0 \rightarrow K^{*0} J/\psi$ and $B^- \rightarrow K^{*-} J/\psi$ come out somewhat larger than the measured branching ratios. This could be changed by adjusting the $B \rightarrow K^*$ form factor by a small amount or may be a sign of the breakdown of the factorization assumption for class II decays [17].

In Table 10 we have collected also the amplitudes proportional to the form factors $V^{B \rightarrow \rho}$, $A_1^{B \rightarrow \rho}$ and $A_2^{B \rightarrow \rho}$. The numbers in the first, second and third column of Table 10 are defined in such a way that the polarization dependent factors $[-\epsilon_{\mu\nu\alpha\beta} \epsilon^{\mu*}(\rho^-) \epsilon^{\nu*}(\rho^+) p_B^\alpha p_{\rho^+}^\beta / (m_B + m_\rho)^2]$ in the term proportional to V in (38), $[\epsilon^*(\rho^+) \epsilon^*(\rho^-)]$ in the term proportional to A_1 in (38) and $[(\epsilon^*(\rho^+) \cdot p_B)(\epsilon^*(\rho^-) \cdot p_B) / (m_B + m_\rho)^2]$ in the term proportional to A_2 in (37) are not included. Except for these factors the amplitudes are of the same order of magnitude as to be expected from the values of the form factors in Table 3. The results in Table 8, 9 and 10 depend on the parameters $A_1^{B \rightarrow \rho}$, $A_2^{B \rightarrow \rho}$, $V^{B \rightarrow \rho}$ and $A_1^{B \rightarrow D^*}$, $A_2^{B \rightarrow D^*}$, $V^{B \rightarrow D^*}$, respectively. The BSW values can be compared to results from other sources, i.e. either other quark models, QCD sum rules or lattice gauge theory. Values for $A_1^{B \rightarrow \rho}$, $A_2^{B \rightarrow \rho}$ and $V^{B \rightarrow \rho}$, reported in the literature, are collected in Table 11. Except for a few cases, the form factors are similar to the BSW values. From lattice gauge theory calculation the following values for $A_1^{B \rightarrow \rho}(0)$ are reported: 0.22 ± 0.05 [35], 0.24 ± 0.12 [36] and $0.27^{+0.07}_{-0.04}$ [52], for a recent review see [21]. A similar collection for $A_1^{B \rightarrow D^*}$, $A_2^{B \rightarrow D^*}$, $V^{B \rightarrow D^*}$ is found in Table 12. $A_0^{B \rightarrow \rho}$ and $A_0^{B \rightarrow D^*}$ can be calculated with the help of (27) from A_1 and A_2 , respectively, given in Table 11 and Table 12.

It is clear that the good agreement of the calculated partial decay rates with the experimental data in the case of the $B \rightarrow PV$ and $B \rightarrow VV$ decays serves only as a consistency

check of the form factors A_1 , A_2 and V for $B \rightarrow \rho$ and $B \rightarrow D^*$. In order to obtain complete information on these form factors many more measurements are needed than just the branching ratios. Additional information can come from decay angular distributions of subsequent decays of the vector mesons. This has been studied in previous work [47, 53] and compared to experimental data in [16].

We are now in the position to calculate other strong coupling constants of the B mesons, which enter into the pole-model formulation of non-leptonic weak decays, on the basis of the information following from the form factors A_1 , A_2 and V for $B \rightarrow \rho$, $B \rightarrow K^*$ and $B \rightarrow D^*$. As a reference we employ the BSW results for these form factors as given in Table 3. It is clear that the calculation can be repeated for any other choice as collected in Table 11 and 12. Let us start with $g_{BB\rho}$. This follows from (29) with the result $g_{BB\rho} = 1.54$. In the same way we obtain $g_{BB_s K^*} = 1.81$ and $g_{BB_c D^*} = 3.48$. We observe a large splitting of the coupling between two pseudoscalar B mesons (BB , BB_s , BB_c) and the vector mesons ρ , K^* and D^* , respectively. This is mainly due to the mass factor of the vector meson in (29).

The other coupling constants which follow from $A_1(0)$ and $A_2(0)$ with the relations (34)

Table 12: Form factors $A_1^{B \rightarrow D^*}$, $A_2^{B \rightarrow D^*}$, $V^{B \rightarrow D^*}$ at $q^2 = 0$ in different models.

Reference	method	$A_1^{B \rightarrow D^*}(0)$	$A_2^{B \rightarrow D^*}(0)$	$V^{B \rightarrow D^*}(0)$
[31]	c	0.46 ± 0.02	0.53 ± 0.09	0.58 ± 0.03
[7]	a	0.651	0.686	0.705
[38]	a	0.62	0.61	0.63
[39]	f	0.622	0.778	0.747

are the coupling constants of axial vector mesons B_1 , B_{s1} and B_{c1} with $B\rho$, BK^* and BD^* , respectively. From $V(0)$ we obtain the coupling constants of the vector mesons B^* , B_s^* and B_c^* with $B\rho$, BK^* and BD^* . The formula for this coupling in the case of $B\rho$ in analogous to the second formula in (34)

$$g = \frac{m_{B^*}^2}{(m_B + m_\rho)f_{B^*}} V^{B \rightarrow \rho}(0). \quad (39)$$

The result of the coupling of the axial vector mesons is:

$$\begin{aligned} g_s(BB_1\rho) &= 10.7, & g_d(BB_1\rho) &= 8.4, \\ g_s(BB_{s1}K^*) &= 11.2, & g_d(BB_{s1}K^*) &= 10.3, \\ g_s(BB_{c1}D^*) &= 14.8, & g_d(BB_{c1}D^*) &= 13.3. \end{aligned}$$

The corresponding vector meson coupling constants are:

$$g(BB^*\rho) = 9.64, \quad g(BB_s^*K^*) = 9.67, \quad g(BB_c^*D^*) = 12.1.$$

We observe that all coupling constants have similar values, of the order of 10. The splitting of the couplings to $B\rho$, BK^* and BD^* is somewhat larger than obtained for the corresponding VPP couplings to $B\pi$, BK and BD in section 2. The coupling constant $g(BB^*\rho)$ can be compared with a QCD sum rule computation of this coupling [54]. Using the values for f_B and f_{B^*} as in our Table 2 these authors obtain $g(BB^*\rho) \simeq 12$ in reasonable agreement with our values above.

4 Summary and Conclusions

We have calculated the branching ratios for the decays of neutral and charged B mesons into PP, PV and VV mesons using two versions of pole-dominance model in addition with a factorization assumption. The first pole model gives the same result as the extensively studied factorization model [7] in terms of current matrix elements, if these current matrix elements are approximated by single poles. The second pole model due to Bedaque et al.[11] employs a different off-mass-shell extrapolation of the residues of the single-pole dominance approximation which leads, besides other differences, to an enhancement of the annihilation diagram contributions. From the derivation we see that the two versions of pole models are related. The pole model of ref.[11] involves a different way of extrapolation away from the pole position which has a particular large effect for some decays where an annihilation contribution is present. In the particular decay $\bar{B}^0 \rightarrow \pi^- D^{*+}$ the model of ref.[11] disagrees with the experimental branching ratios due to a large annihilation contribution. In the cases where annihilation diagrams do not contribute the final results of the two models do not differ very much. For the cases $B \rightarrow VV$ and most of the $B \rightarrow PV$ decays considered in this work they even give identical results.

The coupling constants in the pole model are related to the usual form factors of the current matrix elements at $q^2 = 0$. For an overview we have compared the form factors $F_1^{B \rightarrow \pi}$ and $F_1^{B \rightarrow D}$ and the form factors for the transitions $B \rightarrow \rho$ and $B \rightarrow D^*$ calculated with different methods and found reasonable agreement. Using information for the pseudoscalar and vector meson decay constants we deduced the various strong couplings of the vector mesons B^* , B_s^* and B_c^* with the $B\pi$, BK and BD system, respectively. We found rather similar values for these three couplings showing that the splitting of the form factors $F_1^{B \rightarrow \pi}$, $F_1^{B \rightarrow K}$ and $F_1^{B \rightarrow D}$ is too a large extent related to the splitting of f_{B^*} , $f_{B_s^*}$ and $f_{B_c^*}$. The same pattern evolves for the couplings of the axial-vector mesons B_1 and the vector mesons B^* to the $B\rho$, BK^* and BD^* system. It would be interesting to know whether the relations for the strong coupling constants found in this work could be obtained from QCD sum rule

or lattice calculations.

Acknowledgment

One of us (G.K.) thanks W.F. Palmer for collaboration in the early stages of this work.
